# **Cosmic Ray Electrons and Positrons from Fermi Gamma-Ray Pulsars**

**“Focus on Indirect Dark Matter Searches”**

**IPMU – University of Tokyo**

**Kashiwa, December 11, 2009**

1. (as per talk title) contribution to CR  $e^+e^-$  from **Fermi** gamma-ray **pulsars**

*(work in collaboration with UC Santa Cruz undergrad Lev Gendeleev and grad Michael Dormody)*

2. some thoughts about the “ **Fermi haze** ”

*(work in collaboration with UC Santa Cruz grad Tim Linden)*

- Rotation-powered Pulsars can seed **e<sup>+</sup>e<sup>-</sup>** direct **pair** production

(strong rotationally induced **electric fields** in the magnetosphere accelerate and extract **e<sup>-</sup>** from stellar surface, which radiate **gamma rays**; gammas cascade produce **e<sup>+</sup>e<sup>-</sup> pairs**, escaping the magnetosphere from the polar cap regions)

© Mark A. Garlick / space-art.co.uk

- SNR & PWN shock **acceleration**

## Propagation of charged species: diffusion equation

$$\frac{\partial f}{\partial t} = \frac{D(\gamma)}{r^2} \frac{\partial}{\partial r} r^2 \frac{\partial f}{\partial r} + \frac{\partial (P(\gamma) f)}{\partial \gamma} + Q.$$

$$f(r, t, \gamma)$$

Distribution function

$$\gamma = E_{e\pm} / m_e c^2$$

$$D(\gamma) \propto \gamma^\delta$$

$$P(\gamma) = p_0 + p_1 \gamma + p_2 \gamma^2$$

0: Coulomb; 1: Brems; 2: IC & Synch

(\*) Atoyan, Aharonian, Volk, 1995

Approximate **solution** to the electron/positron distribution function<sup>(\*)</sup>  
 (only IC and Synch losses – burst-like injection)

$$f(r, t, \gamma) = \frac{N_0 \gamma^{-\alpha}}{\pi^{3/2} r^3} (1 - p_2 t \gamma)^{\alpha-2} \left( \frac{r}{r_{\text{dif}}} \right)^3 e^{-(r/r_{\text{dif}})^2}$$

$$\gamma < \gamma_{\text{cut}} \equiv \gamma_{\text{cut}}(t) = (p_2 t)^{-1}$$

$$p_2 = 5.2 \times 10^{-20} \frac{w_0}{1 \text{ eV/cm}^3} \text{ s}^{-1}$$

**Cut-off in  
Energy →  
Pulsar Lifetime**

$$r_{\text{dif}}(\gamma, t) \simeq 2 \sqrt{D(\gamma) t \frac{1 - (1 - \gamma/\gamma_{\text{cut}})^{1-\delta}}{(1 - \delta) \gamma/\gamma_{\text{cut}}}}.$$

**Cut-off in Space**

(\*) Atoyan, Aharonian, Volk, 1995

**Main feature of high-energy (10-1000 GeV)  $e^+e^-$ :**  
**they *lose energy* very *efficiently***

Energy losses  $\sim E^2$ , via synchrotron and inverse Compton

$$\frac{t_{\text{Lifetime}}}{\text{yr}} \approx 5 \times 10^5 \left( \frac{1 \text{ TeV}}{E} \right) \left[ \left( \frac{B}{5 \mu\text{G}} \right)^2 + 1.6 \times \left( \frac{w}{1 \text{ eV/cm}^3} \right) \right]^{-1}$$

In conjunction with conventional diffusion models, this short radiative cooling time limits the sources of high energy electron/positron both in **space and time**

$$\text{dist}_{\text{max}} \approx \sqrt{D_0 \times t} \approx 100 - 500 \text{ pc} \quad [D_0 \approx 10^{28} \text{ cm}^2/\text{s}]$$

Astrophysical sources relevant for energetic  $e^+e^-$  production must be **young** ( $\sim 10^5$  yr) and **nearby** ( $< \text{kpc}$ )

Example of a **burst**-like injection at different **times**,  
 $r = 100$  pc, injection power-law: 2.2

**Distance** sets normalization, and affects spectrum,  
(  $s = r/r_{dif}$  , and more distant, more peaked)

(\*) Atoyan, Aharonian, Volk, 1995

## The effects of a **non-burst-like** injection

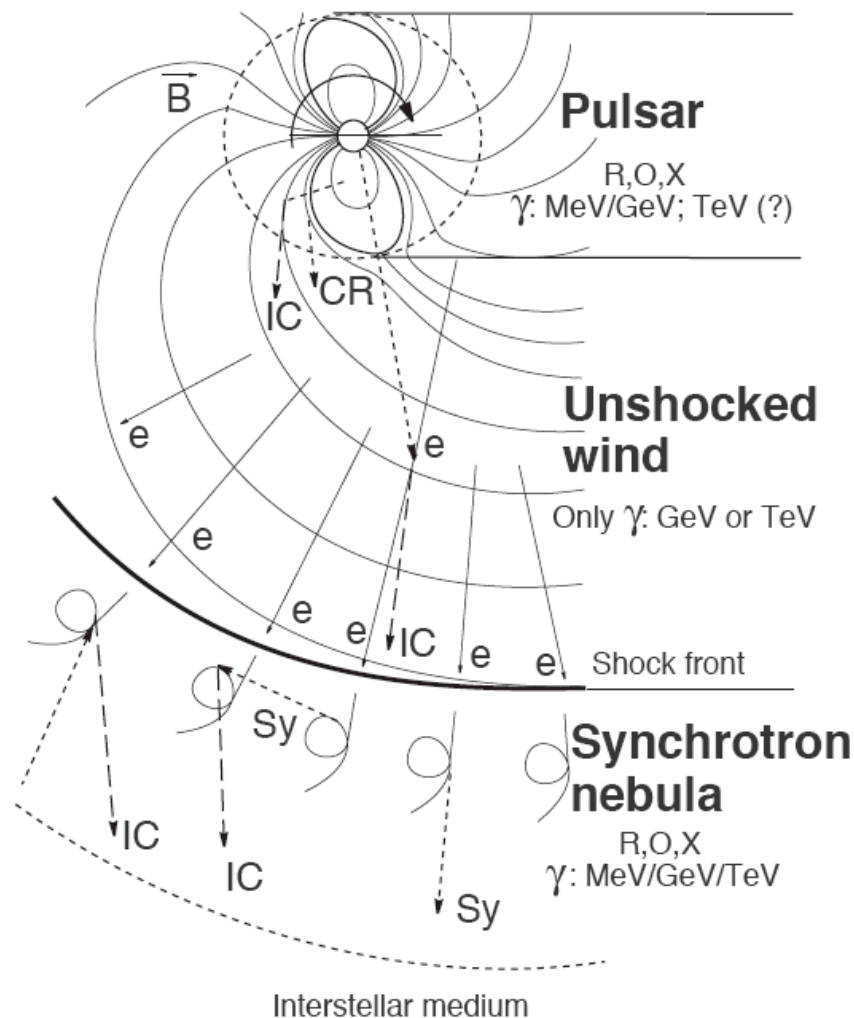

in Fig. 4 represent the fluxes of electrons from the source at the same distance  $r = 100$  pc and of age  $t = 10^5$  yr continuously injecting relativistic electrons with the power-law index  $\alpha = 2.2$  into ISM, but with the total luminosity varying in time during  $0 \leq \tau \leq t$  as

$$L_e(\tau) = \frac{L_0}{(1 + \tau/\tau_*)^k} \quad (24)$$

for three different values of the characteristic “decay” time  $\tau_*$ :  $\tau_*/t = 0.1$  (curve 1),  $\tau_*/t = 0.01$  (curve 2),  $\tau_*/t = 0.001$  (curve 3). This kind of time-dependent in-

## Radiation from a **Pulsar-wind-nebula** complex

Electromagnetic processes and **emission** in a pulsar environment

Multi-Wavelength observations help:

(i) set the scale of the **total power** in relativistic  $e^+e^-$

(ii) understand the  $e^+e^-$  **spectrum**

examples:

- HESS J1825-137
- Vela X (HESS)
- Geminga (Milagro)

(\*) Aharonian and Bogovalov, 2002

An **asset** of the pulsar scenario:  
pulsars **exist**, detailed **catalogues**, very **accurate** data

Atlas of known (**yellow**) and predicted  
galactic radio pulsars

Region relevant for Pamela  
and Fermi  $\sim 1\text{--}2$  kpc from Sun

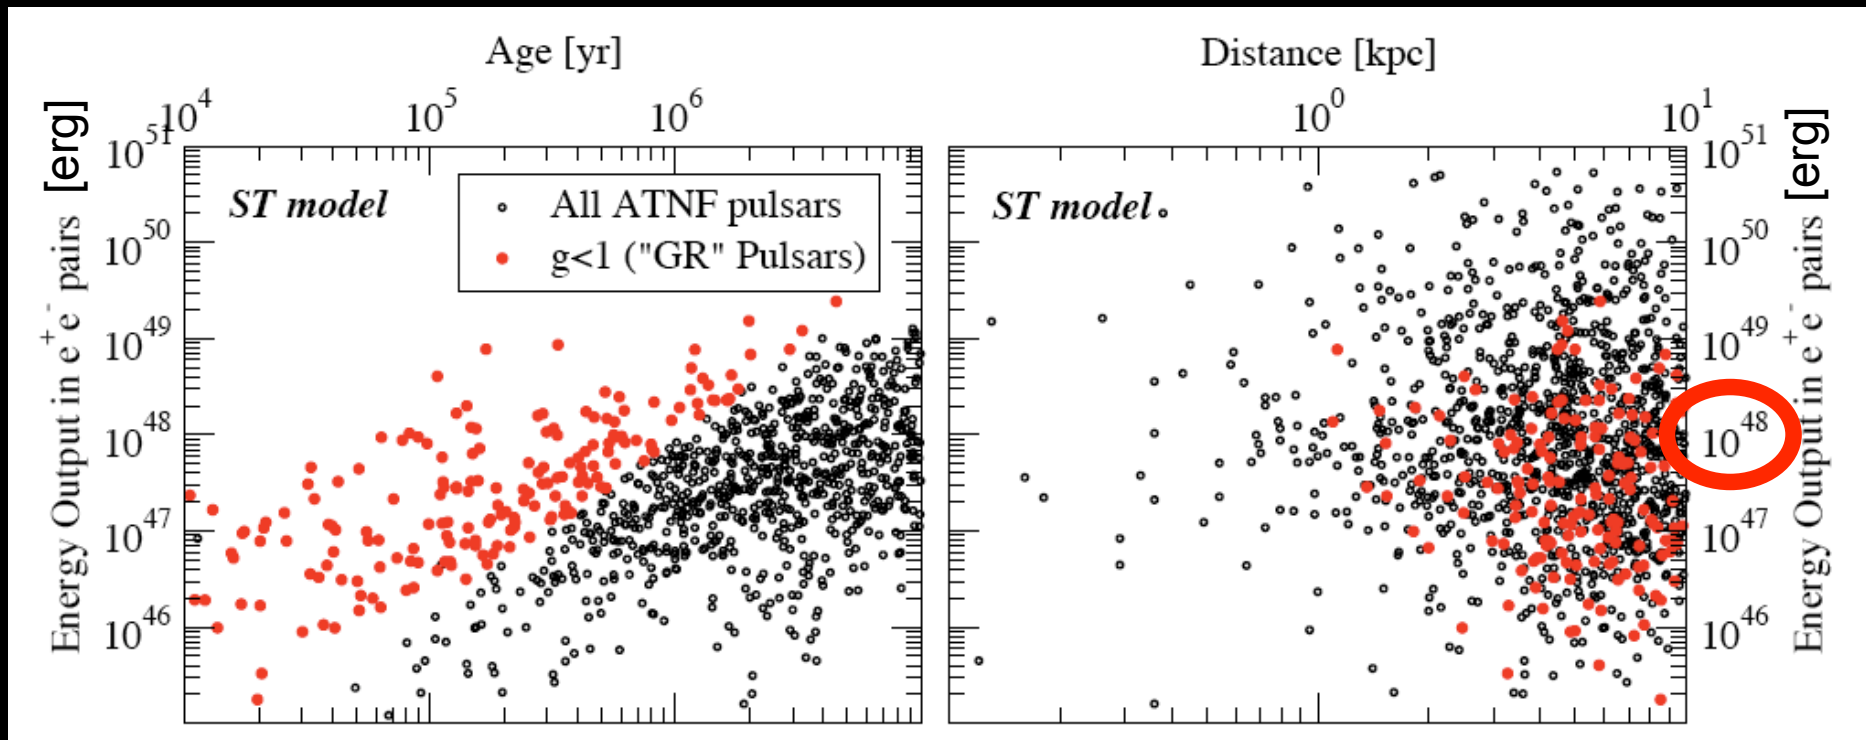

Not all pulsars are **gamma-ray** (and e+e-) pulsars

E.g., in the outer gap model, **pair** production sets in if

$$E_x E_\gamma > m_e^2$$

This condition depends on **magnetic field** intensity and period

$$g = 5.5 P^{26/21} B_{12}^{-4/7} < 1.$$

## Role of **Fermi** to assess the **origin** of high-energy **CRE**:

1. Accurate CRE **Spectral Information** (probably not conclusive by itself)
2. **Local** CRE **source** ? → Compare the **Inverse Compton** and **Bremss.** emis. predicted from the measured CRE spectrum with diffuse **gamma-ray data**
3. **Anisotropy**: search for excess CRE from bright nearby **pulsars**  
(problem: pulsar proper motion !!  
also ongoing: East-West asymmetry search !!)
4. Discovery and improved understanding of **gamma-ray pulsars**,  
guaranteed sources of  $e^+e^-$

# The Fermi First **Pulsar Catalogue**

- Includes high-confidence (>) pulsed sources in the first **6-months** of data
- **16 gamma-ray** selected  
(majority from blind-search campaign)
- **24 radio-selected**  
(via ephemerides, and of which 8 millisecond)
- **6 pre-Fermi GR pulsars**

Fig. 3.— Galactic plane pulsar distribution (polar view). The star represents the Galactic center. The two circles centered at the Earth's position have radii of 3 kpc and 5 kpc. For pulsars with different possible distances, the nearer values from Table 5 are used. Note that the millisecond pulsars (MSPs), while having a significantly lower  $\dot{E}$  than the other pulsars (see Figure 8), are detectable due to their close proximity. The one exception (PSR J0218+4232) also exhibits a significantly higher  $\dot{E}$  than the other MSPs. Blue squares: gamma-ray-selected pulsars. Red triangles: millisecond gamma-ray pulsars. Green circles: all other radio loud gamma-ray pulsars. Black dots: Pulsars for which gamma-ray pulsation searches were conducted using rotational ephemerides. Gray dots: Known pulsars which were not searched for pulsations.

10 **Abstract.** We analyze the contribution of gamma-ray pulsars from the first Fermi-  
11 Large Area Telescope (LAT) catalogue to the local flux of electrons and positrons  
12 ( $e^+e^-$ ). We present new distance estimates for all Fermi gamma-ray pulsars based

**Main results:**

- gamma-ray pulsar contribution can be **substantial** from **10** of the brightest Fermi pulsars
- **6/10** are blind-search **gamma-ray selected** pulsars
- outline of regions where **radio-pulsars** might contribute without a gamma-ray signal

$$L_\gamma \approx w\dot{E} \approx C \times \left( \frac{\dot{E}}{10^{33} \text{ ergs}^{-1}} \right)^{1/2} \times 10^{33} \text{ ergs}^{-1}$$

$w$  : Gamma-Ray **conversion efficiency**

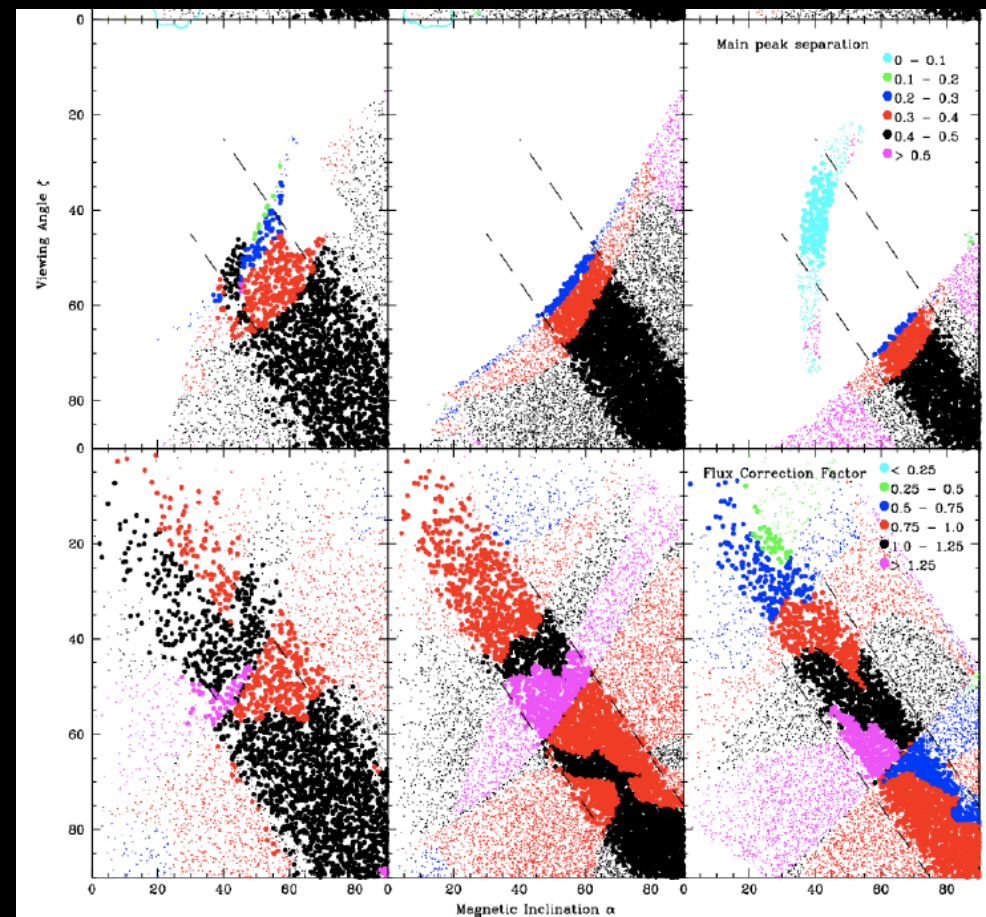

$C$  : constant of  $O(1)$  – **fitted** with PSR subset with solid distance determinations

$$L_\gamma = 4\pi f_\Omega D^2 F_\gamma,$$

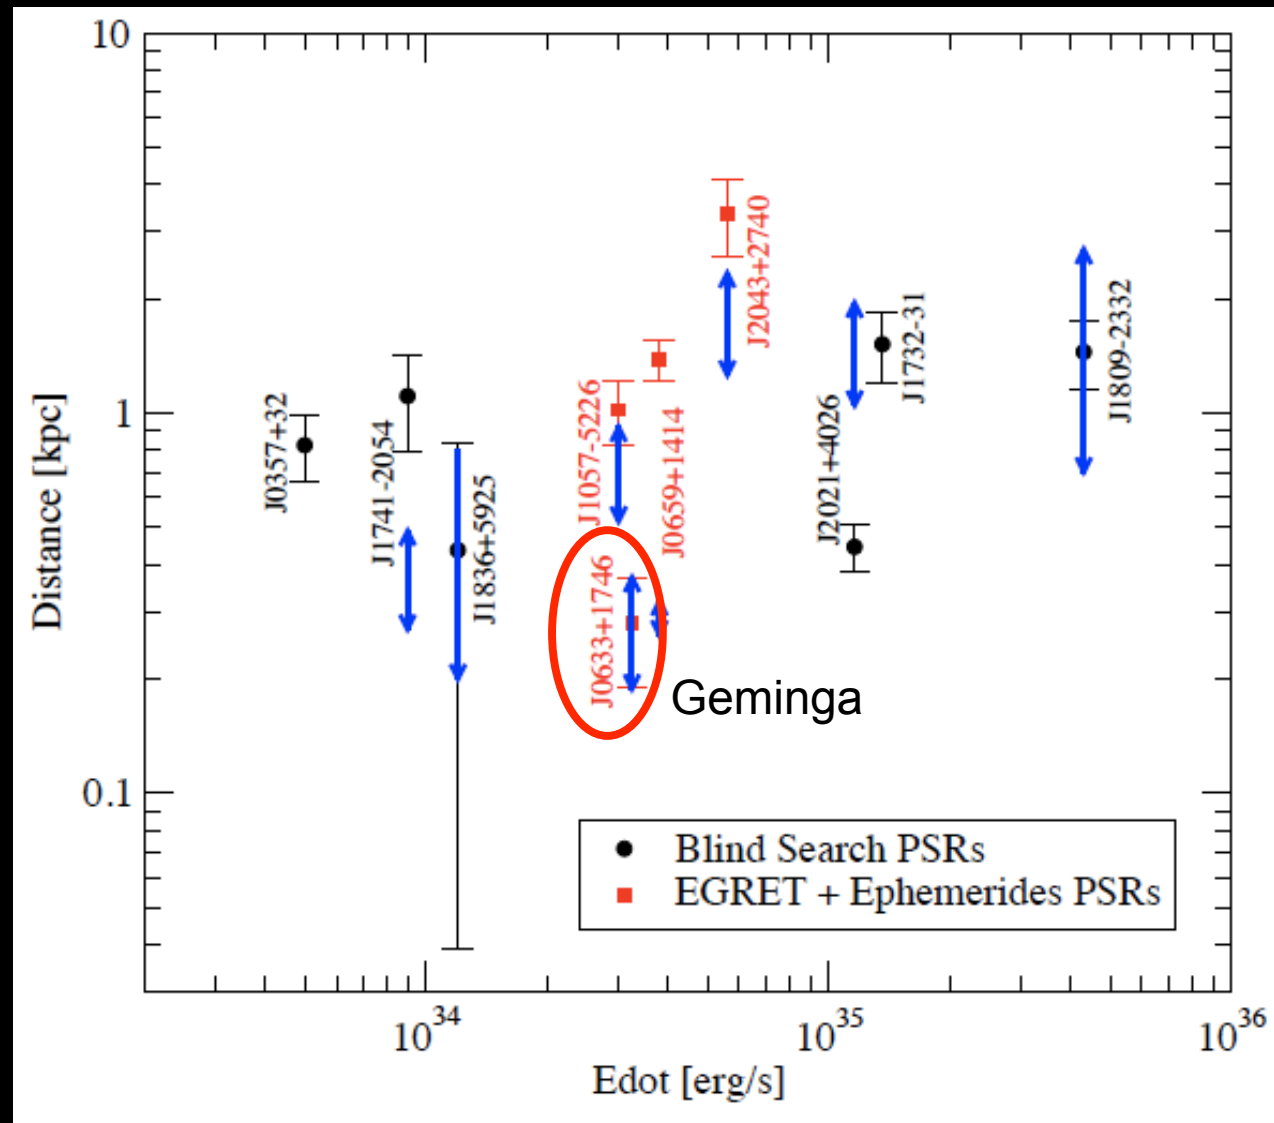

$f_\Omega$ : flux correction factor –  
from Watters et al “**Atlas**”

$$f_\Omega = f_\Omega(\alpha, \zeta_E) = \frac{\iint F_\gamma(\alpha, \zeta, \phi) \sin(\zeta) d\zeta d\phi}{2 \int F_\gamma(\alpha, \zeta_E, \phi) d\phi}.$$

plus: standard error propagation

# Distance Determinations: Results

## Contribution to the local e<sup>+</sup>e<sup>-</sup> Flux

$$Q(E, t, \vec{r}) = Q_0 \left( \frac{E}{1 \text{ GeV}} \right)^{-\Gamma} \exp[-E/E_{\text{cut}}] \delta(t - t_0) \delta(\vec{r})$$

$$E_{\text{cut}} = 1 \text{ TeV}, \quad \Gamma = 1.7.$$

$$\int_{m_e}^{\infty} Q(E) dE = E_{\text{out}} = \eta \frac{\dot{E} t_{\text{ch}}^2}{\tau}, \quad \text{with } \tau \simeq 10^4 \text{ yr and } \eta = 0.4.$$

$$\frac{\partial N_e(E, t, \vec{r})}{\partial t} - D(E) \nabla^2 N_e - \frac{\partial}{\partial E} (b(E) N_e) = Q(E, t, \vec{r}),$$

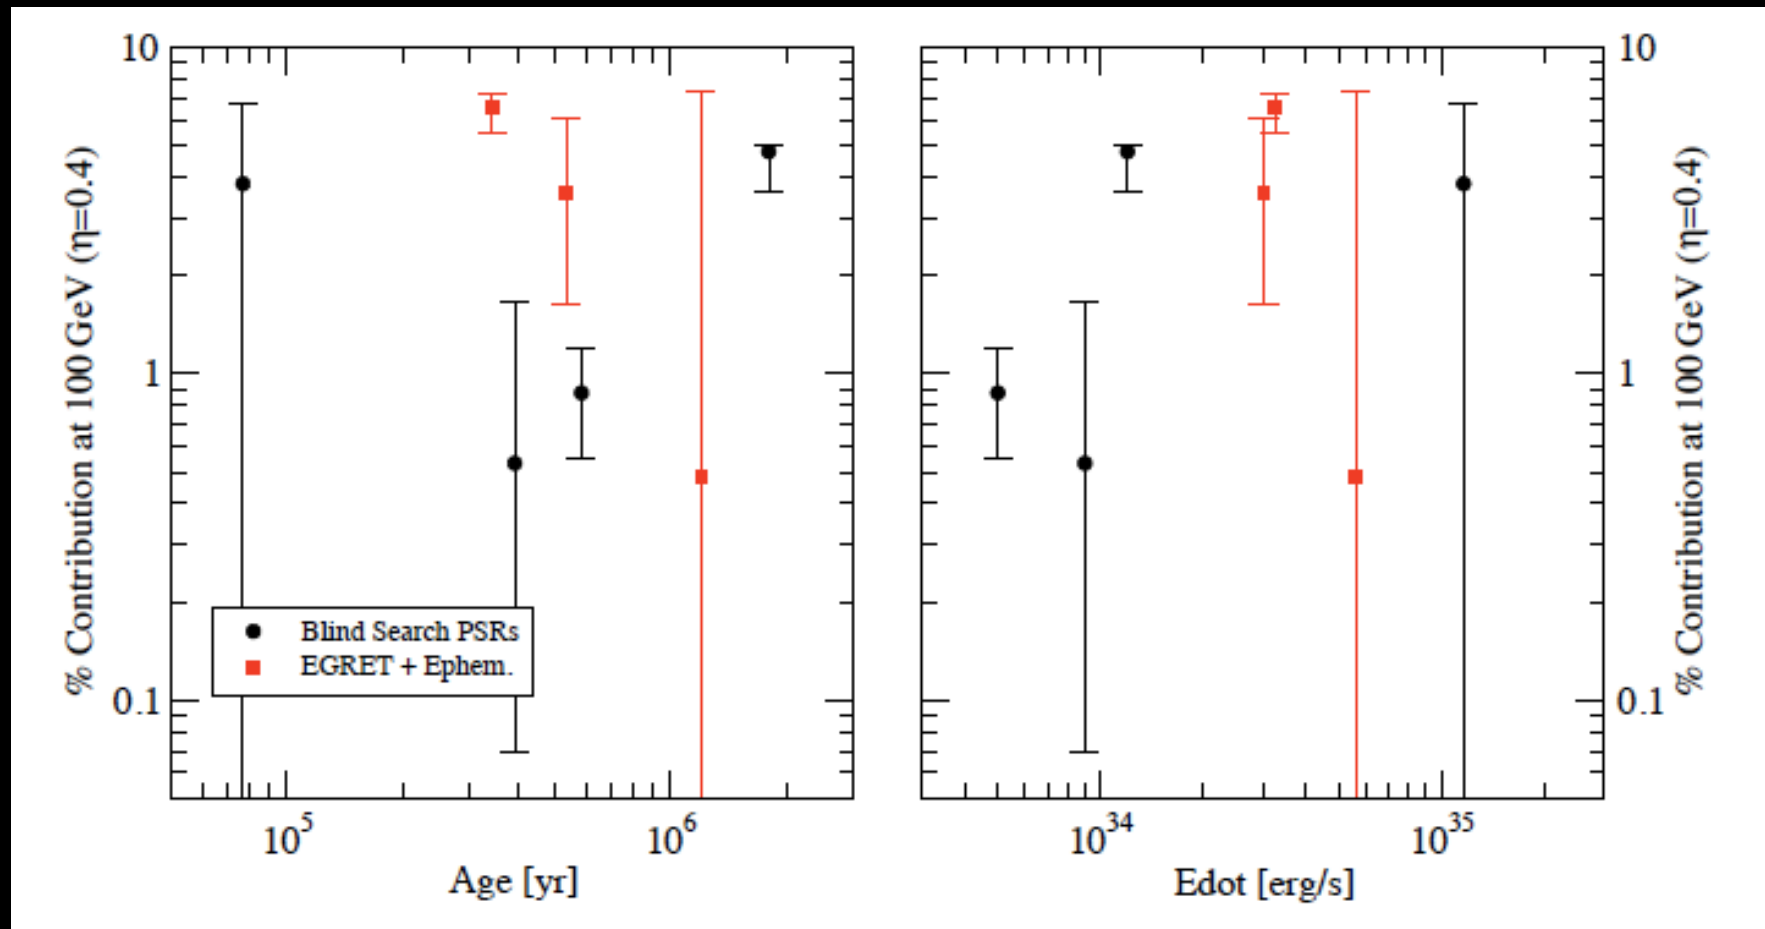

$$D(E) = D_0 (E/1 \text{ GeV})^\delta$$

$$D_0 = 3.6 \times 10^{28} \text{ cm}^2/\text{s} \text{ and } \delta = 0.33$$

## Contribution to the local $e^+e^-$ Flux

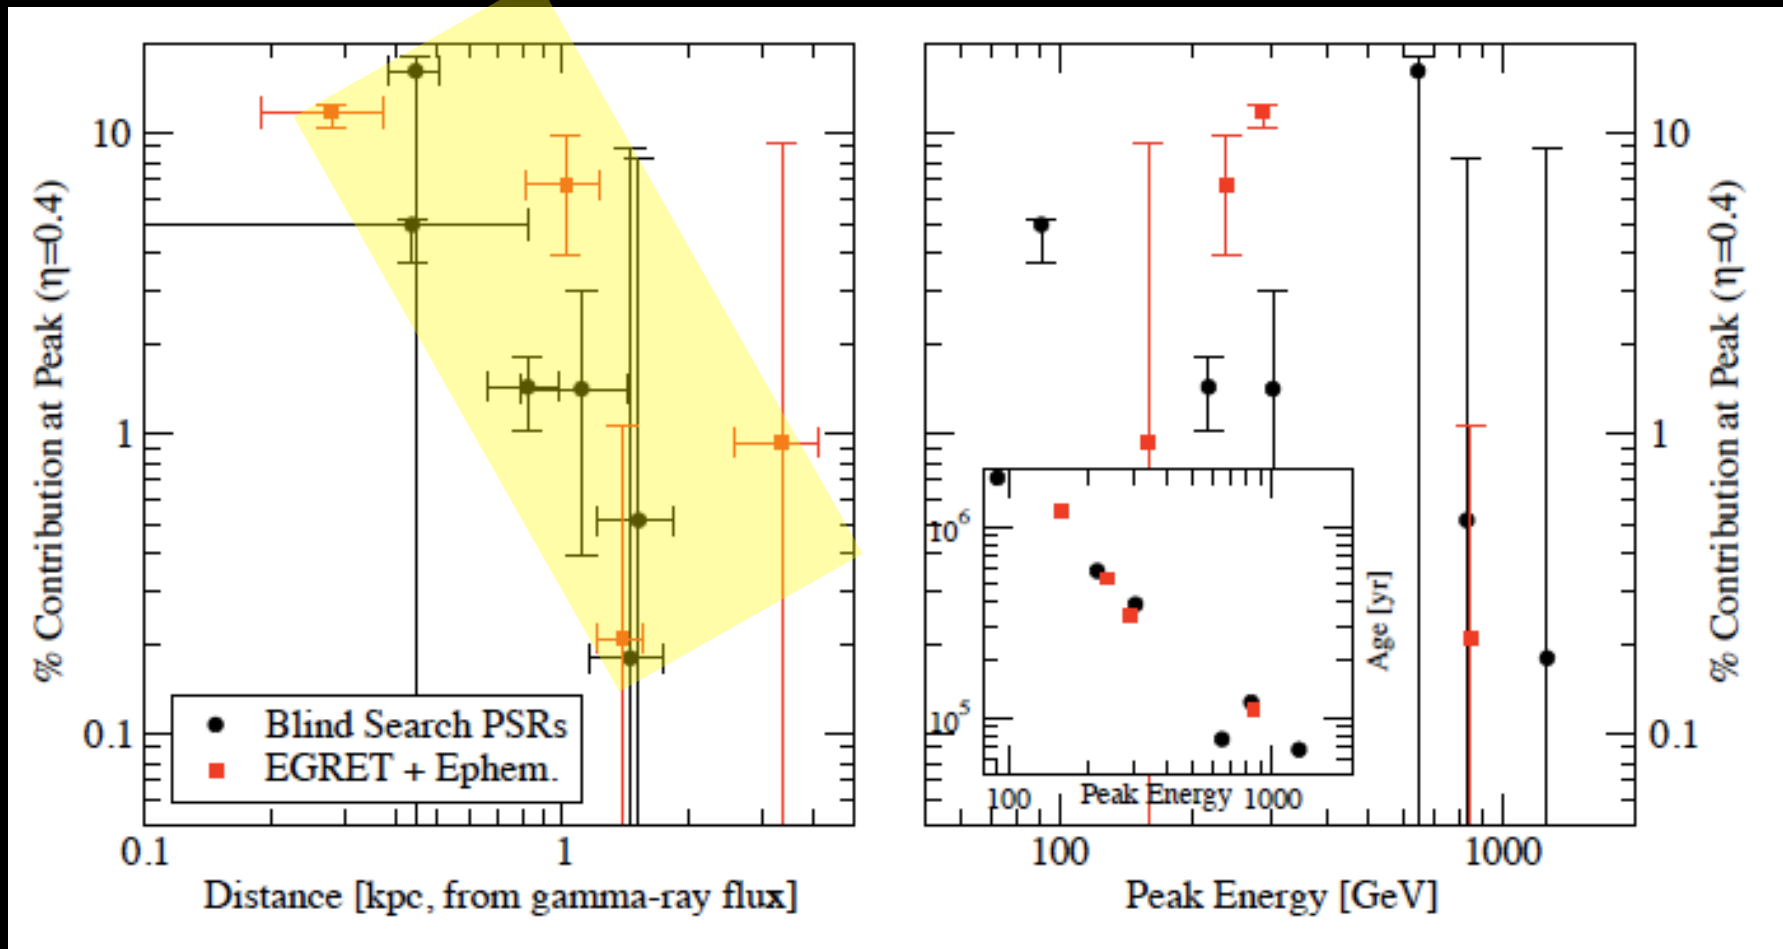

## Contribution to the local $e^+e^-$ Flux – a closer look (1)

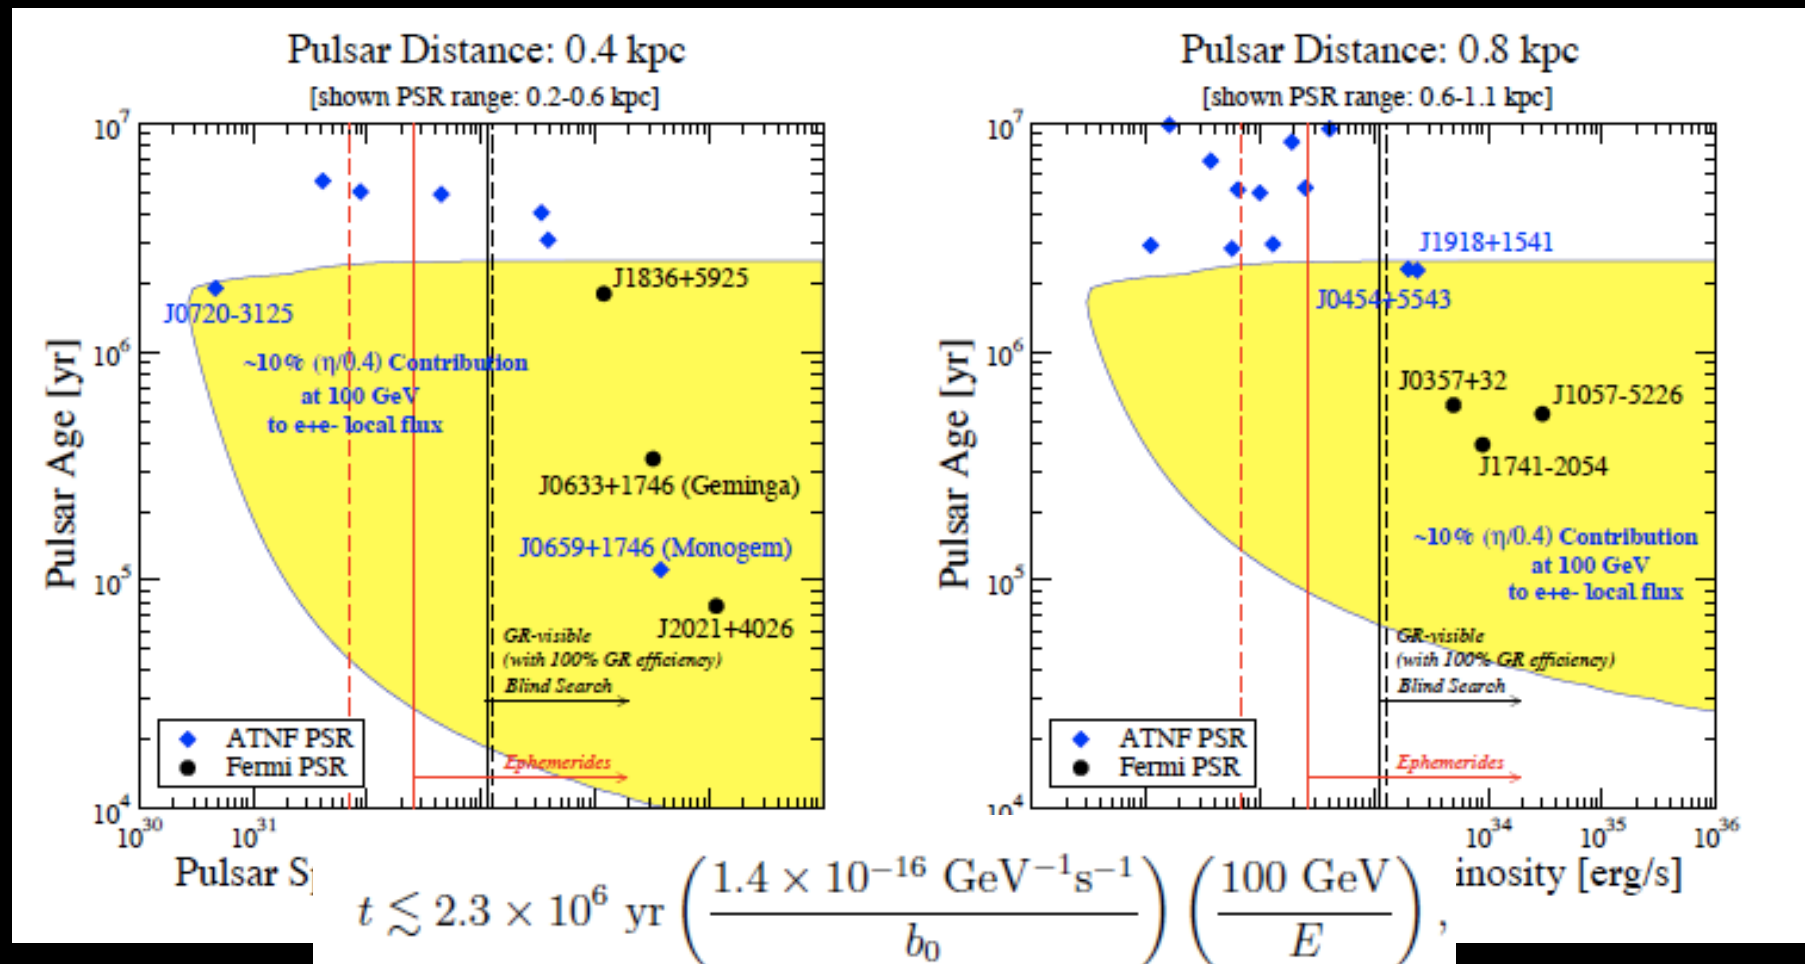

- Rather narrow **age** and **spin-down luminosity** ranges
- **flat contribution** over those ranges

## Contribution to the local $e^+e^-$ Flux – a closer look (2)

- Steeply **declining** contribution **with distance**
- Largest contributions between **100 and 1000 GeV**

Do we expect known **radio pulsar** (~1,500) to be still more important than ~50 **gamma-ray pulsars**?

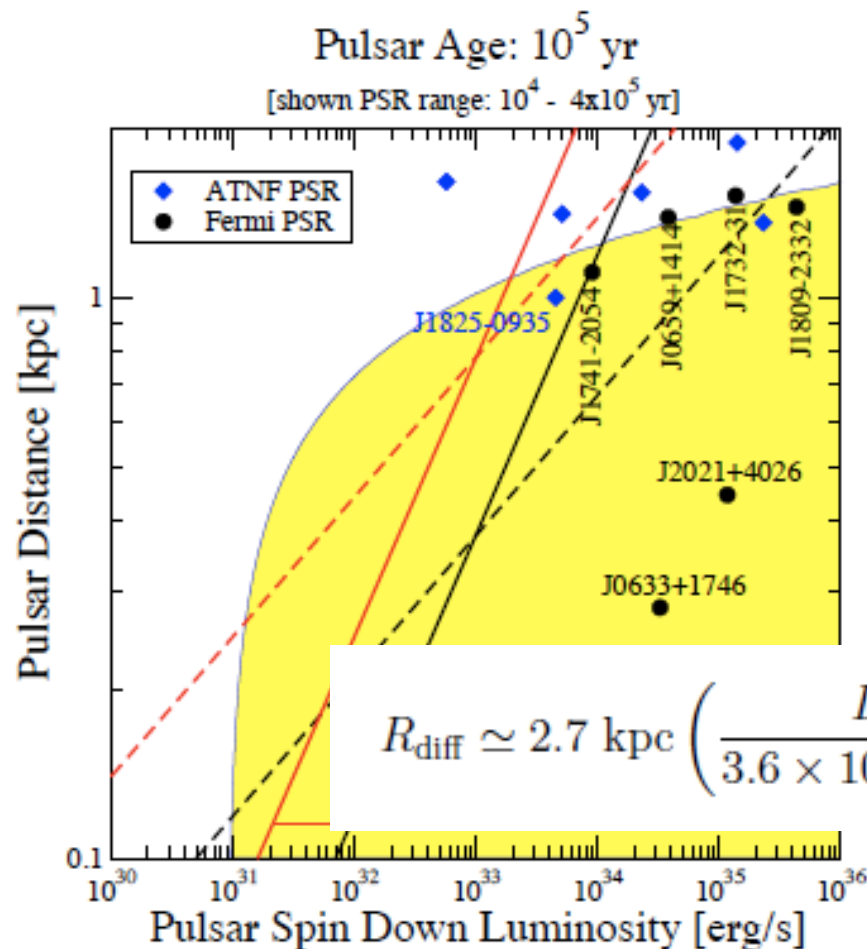

$$R_{\text{diff}} \simeq 0.5 \text{ kpc} \left( \frac{D_0}{3.6 \times 10^{28} \text{ cm}^2/\text{s}} \frac{t}{10^5 \text{ yr}} \right)^{1/2} \left( \frac{100 \text{ GeV}}{E} \right)^{\delta/2}$$

$$E \ll E_{\text{max}} = (b_0 t)^{-1}$$

Do we expect known **radio pulsar** (~1,500) to be still more important than ~50 **gamma-ray pulsars**?

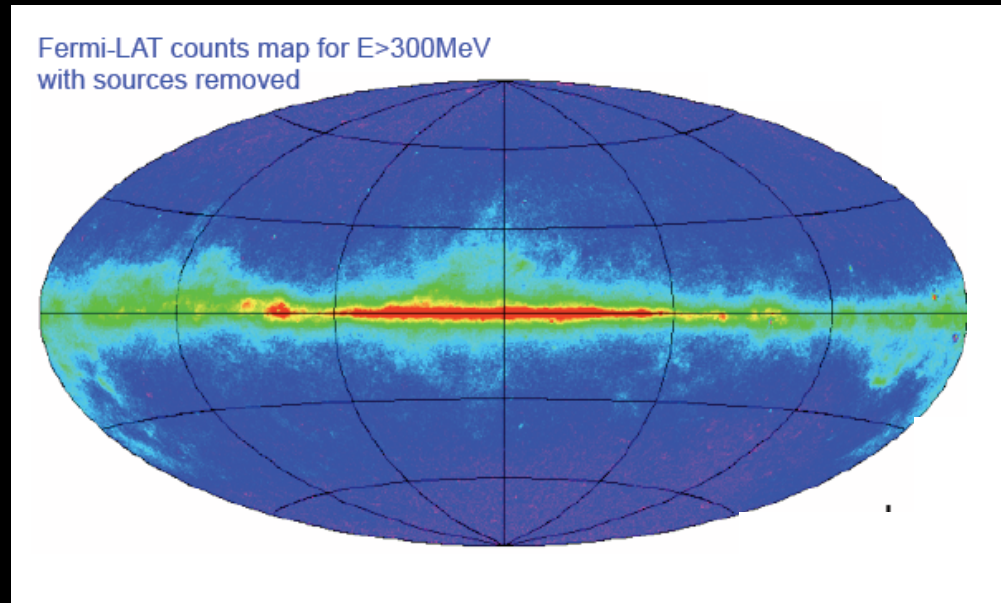

There is parameter space where gamma-ray quiet pulsars could significantly contribute!

$$E/E_{\max} \simeq 1.$$

$$R_{\text{diff}} \simeq 2.7 \text{ kpc} \left( \frac{D_0}{3.6 \times 10^{28} \text{ cm}^2/\text{s}} \frac{1.4 \times 10^{-16} \text{ s}}{b_0} \right)^{1/2} \left( \frac{100 \text{ GeV}}{E} \right)^{1-\delta}.$$

$$N_e \propto \exp[-(r/R_{\text{diff}})^2]$$

# Some thoughts about the “**Fermi haze**”

Three main contributions to the **diffuse** gamma-ray **emission**:

- **Galactic** emission
  - Neutral Pions – inelastic hadronic cosmic-ray processes
  - $e^+e^-$  Radiative Losses: Inverse Compton & Bremsstrahlung
- **Isotropic** emission (extra-galactic + cosmic ray mis-ID)

(\*) J-M Casandjian, Fermi Symposium 2009

# The standard **full-glory** approach

[slide from Igor Moskalenko]

Is there an **excess** gamma-ray diffuse **emission**?  
Relevant for:  $e^+e^-$  responsible for the haze, DM annihilation

Dobler et al: simple diagnostic:  
fit **spatial templates** to Fermi gamma-ray sky

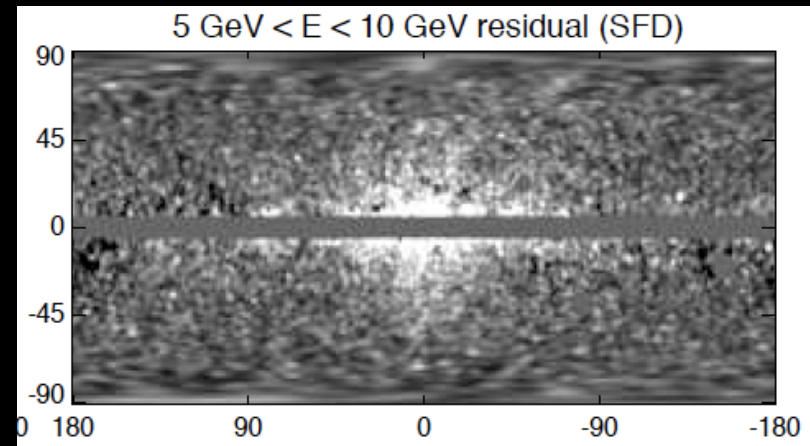

**Dust** (far IR 100  $\mu$  emission)  
 $\Rightarrow$  ISM Gas  $\Rightarrow \pi^0$  (no CR sources!)

**Synchrotron** emission map  
 $\Rightarrow$  **IC** emission (same  $e^+e^-$ , but...)

(\*) Dobler et al, 0910.4583

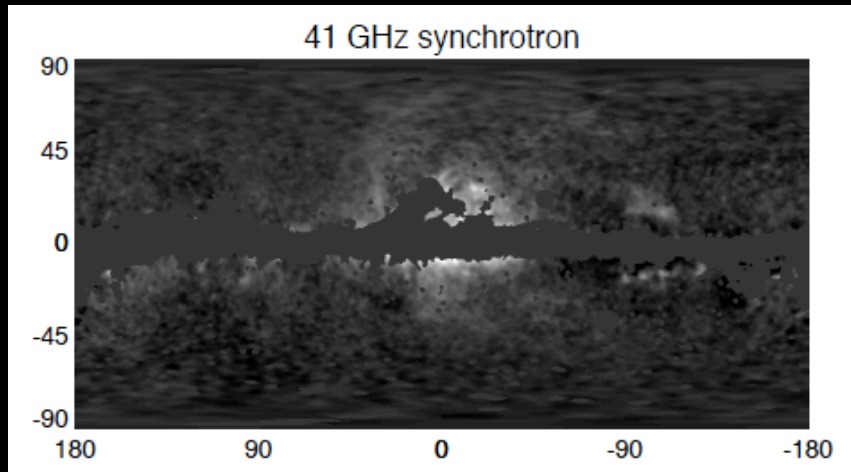

Large **residuals** in a region morphologically comparable  
to the microwave **WMAP haze** excess

(\*) Dobler et al, 0910.4583

The resulting “Fermi haze” has an intriguing **morphology**

Try to fit with a **bi-variate gaussian**  
additional diffuse component  
(expected from e.g.  $e^+e^-$  producing  
WMAP haze, or DM secondaries)

(\*) Dobler et al, 0910.4583

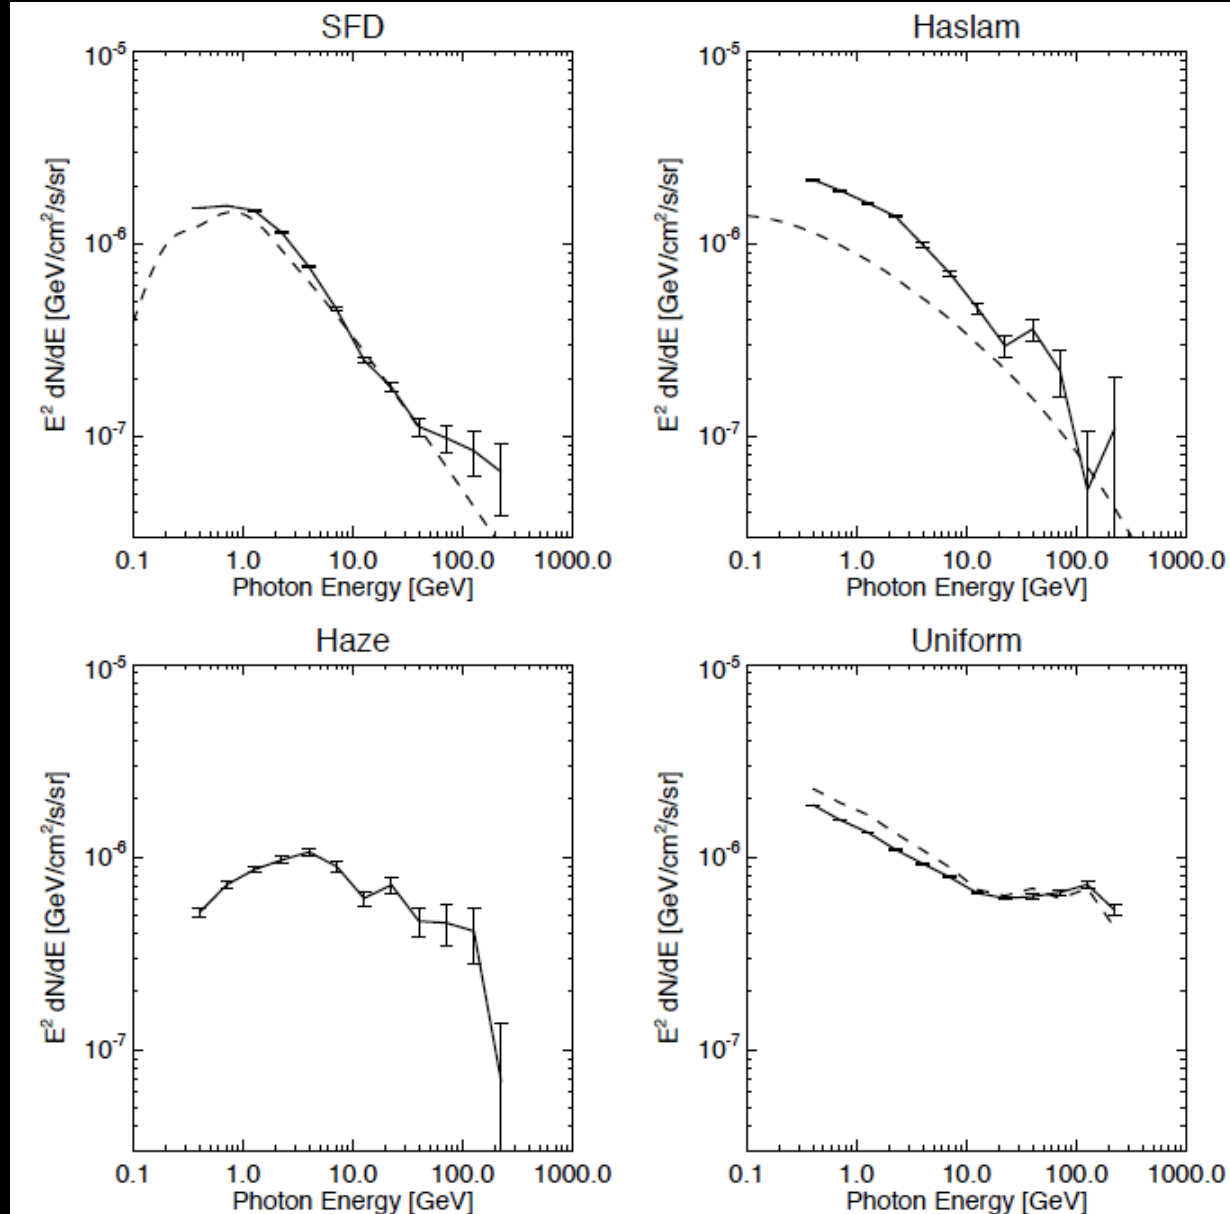

The resulting “Fermi haze” has an intriguing **morphology**

Try to fit with a **bi-variate gaussian**  
additional diffuse component  
(expected from e.g.  $e^+e^-$  producing  
WMAP haze, or DM secondaries)

(\*) Dobler et al, 0910.4583

Residuals are now  
at a “noise” level –  
**satisfactory fit!**

Proceed to use  
the relative  
normalization to  
calculate **spectra**

(\*) Dobler et al, 0910.4583

Are **spatial templates** accurate enough to claim a Fermi haze?

**Test quantitatively** by employing the predictions of the full-glory approach

**First template - First assumption:** gas (dust) traces  $\pi^0$ 's

Regions  
used to  
**normalize**

Map (norm. to 1) of ratio of  $\pi^0$ 's to **ISM** col. dens.

Issue: **cosmic rays sources** live in the haze region!

## Second Template - Second Assumption: Synchrotron traces IC

Issue: while both are sourced by  $e^+e^-$ , the emissions follow the magnetic field and inter-stellar radiation field energy densities with potentially very **different morphologies!**

## Second Template - Second Assumption: Synchrotron traces IC

Try a **constant** magnetic field model  
(retaining a detailed **ISRF** model)  
again, produce an artificial haze

## Second Template - Second Assumption: Synchrotron traces IC

Assuming a “**sharper**” galactic magnetic field model  
(smaller  $z$  scale) one produces again an  
(energy-dependent) **artificial haze**

**Systematic effects** in the spatial templates  
**artificially** produce a **haze**  
and affect the low-energy determination of an excess

At large energies: very **low statistics** +  
very large **cosmic ray** contamination

A **full-glory** galactic cosmic ray simulation is necessary

but is it **sufficient**?!

# **Fermi** gamma-ray sky (source subtracted) and **Galprop** predictions

(from Casandjian, poster @ Fermi Symposium, 2009)

Fermi-LAT counts map for  $E > 300 \text{ MeV}$   
with sources removed

diffuse model counts prediction  
for  $E > 300 \text{ MeV}$

(\*) J-M Casandjian, Fermi Symposium 2009

The **residuals** trace the polarized synchrotron emission presumably from the nearby **Loop I** (North Polar Spur) supernova shell (~100 deg!!)

**local** cosmic ray **structure** maybe key to understand the diffuse emission beyond galactic cosmic ray simulations and models

Residual map (data-model) for photons with  $E > 300$  MeV

WMAP 23GHz polarized intensity convolved with Fermi-LAT PSF for  $E > 300$  MeV

Unfortunately charged cosmic rays don't travel **straight lines**  
and they are sometimes not produced by our **favorite sources...**

Unfortunately charged cosmic rays don't travel **straight lines**  
and they are sometimes not produced by our **favorite sources...**

Yet, the field is in the midst of a **unique** and **exciting spur of data**

Unfortunately charged cosmic rays don't travel **straight lines**  
and they are sometimes not produced by our **favorite sources...**

Yet, the field is in the midst of a **unique** and **exciting spur of data**

A solid prediction: **boredom not in sight for theorists!**
