Introduction

Part I: Holographic dictionary

Part II: New holographic models

Conclusions

# Planck (2009)

# Primordial perturbations

The primordial perturbations offer some of our best clues as to the fundamental physics underlying the big bang. Their form appears to be very simple:

- Small amplitude:  $\delta T/T \sim 10^{-5}$ .
- *Nearly* Gaussian.
- *Nearly* scale-invariant.
- Adiabatic.

Any proposed cosmological model must be able to account for these basic features, and any predicted deviations (*e.g.* from Gaussianity) are likely to prove critical in distinguishing different models.

# The primordial power spectrum

A Gaussian distribution is fully characterised by its 2-point function or power spectrum. From observations, the power spectrum takes the form:

$$\Delta_S^2(q) = \Delta_S^2(q_0) (q/q_0)^{n_s(q)-1}$$

The WMAP data yield (for  $q_0 = 0.002\text{Mpc}^{-1}$ )

$$\Delta_S^2(q_0) = (2.445 \pm 0.096) \times 10^{-9}, \quad n_s - 1 = -0.040 \pm 0.013,$$

*i.e.*, the scalar perturbations have **small amplitude** and are **nearly scale invariant**.

- These two small numbers should appear **naturally in any theory that explains the data**.

# Non-Gaussianity

Non-Gaussianity implies non-zero higher-point correlation functions. The lowest order is the 3-point function, or **bispectrum**, of curvature perturbations  $\zeta$ :

$$\langle \zeta(q_1)\zeta(q_2)\zeta(q_3) \rangle = (2\pi)^3 \delta(\sum q_i) B(q_i)$$

Non-Gaussianity arises from **nonlinearities** in cosmological evolution. The three main sources are:

1. Nonlinearities (interactions) in inflationary dynamics.
2. Nonlinear evolution of perturbations in radiation/matter era.
3. Nonlinearities in relationship between metric perturbations and CMB temperature fluctuations. (To linear order,  $\Delta T/T = (1/3)\Phi$ ).

# Non-Gaussianity

- Non-Gaussianity is important as it potentially provides a *very strong* test of inflationary models. The amplitude of the bispectrum is parametrised by  $f_{NL}$ :

$$B(q_i) = f_{NL} \times (\text{shape function})$$

- Different inflationary models give different predictions for  $f_{NL}$  and shape function.

# The shape of non-Gaussianity

- Local form [Gangui etal (1994)]; [Verde etal(2000)] ; Komatsu & Spergel (2001)]

$$B_{\text{local}}(q_1, q_2, q_3) = f_{NL}^{\text{local}} \frac{6A^2}{5q_1^3 q_2^3 q_3^3} \sum_{i=1}^3 q_i^3, \quad A = 2\pi^2 \Delta_S^2(q)$$

→ WMAP7:  $f_{NL}^{\text{local}} = 32 \pm 21 (68\%CL)$

→ Single scalar slow-roll inflation:  $f_{NL}^{\text{local}} \sim O(\epsilon, \eta) \sim 0.01$

- Equilateral form [Creminelli etal, astro-ph/0509029]

$$B_{\text{equil}}(q_1, q_2, q_3) = f_{NL}^{\text{equil}} \frac{18A^2}{5q_1^3 q_2^3 q_3^3} \left( -2q_1 q_2 q_3 - \sum_{i=1}^3 q_i^3 + (q_1 q_2^2 + 5 \text{ perm}) \right)$$

→ WMAP7:  $f_{NL}^{\text{equil}} = 26 \pm 140 (68\%CL)$

- The Planck data (expected next year) should be sensitive to just

$$f_{NL} \sim 5.$$

# Holographic Universe

In this talk I will present new holographic models for the very early universe:

- In these models, the very early universe is **non-geometric** and has a weakly coupled description in terms of a **three dimensional QFT**.
- They provide a **new mechanism** for a scale invariant spectrum.
- They are compatible with current observations, yet they have **different phenomenology than conventional inflation**.

# References

# Holography for cosmology

Any holographic proposal for **cosmology** should specify

- 1 what the dual QFT is
- 2 how it can be used to compute **cosmological observables** (*the holographic dictionary*)

Having defined the duality,

- the new description should **recover established results** in the regime where the **weakly coupled** gravitational description is valid
- **new results** should follow by using the duality in the regime where **gravity is strongly coupled**.

# Main results

Our two main results are:

**Standard inflation is holographic.**

There are **holographic models** that have **different phenomenology** than slow-roll inflation but they are nevertheless **consistent with current observations**. The Planck data has the power to comfortably refute or confirm these models.

# Plan

In the first part, I will explain the sense in which **inflation is holographic**.

- Review standard inflationary computations.
- Review how to compute strong coupling QFT results using **standard gauge/gravity duality**.
- Show that the inflationary results can be fully expressed in terms of **correlators of strongly coupled QFTs**.

In the second part, I will discuss the new holographic models. While standard inflation is linked to strongly coupled QFTs, the new models are based on **weakly coupled three dimensional QFT**.

## 3 Part II: New holographic models

## 4 Conclusions

# Cosmological Perturbations

We start by reviewing **standard inflationary cosmology**.

- We will discuss (for simplicity) **single field four dimensional** inflationary models,

$$S = \frac{1}{2\kappa^2} \int d^4x \sqrt{-g} (R - (\partial\Phi)^2 - 2\kappa^2 V(\Phi))$$

- We assume a **spatially flat background** (for simplicity)

$$\begin{aligned} ds^2 &= -dt^2 + a^2(t) dx^i dx^i \\ \Phi &= \varphi(t) \end{aligned}$$

- The physical degrees of freedom are a **scalar field  $\zeta$**  and a **transverse traceless metric  $\gamma_{ij}$** .

# Power spectrum

In the inflationary paradigm, cosmological perturbations are assumed to originate at sub-horizon scales as **quantum fluctuations**.

- Quantising the perturbations in the usual manner,

$$\begin{aligned}\langle \zeta(t, \vec{q}) \zeta(t, -\vec{q}) \rangle &= |\zeta_q(t)|^2 \\ \langle \gamma_{ij}(t, \vec{q}) \gamma_{kl}(t, -\vec{q}) \rangle &= 2|\gamma_q(t)|^2 \Pi_{ijkl},\end{aligned}$$

where  $\Pi_{ijkl}$  is the transverse traceless projection operator and  $\zeta_q(t)$  and  $\gamma_q(t)$  are the mode functions.

- The superhorizon **power spectra** are obtained by

$$\Delta_S^2(q) = \frac{q^3}{2\pi^2} |\zeta_q(0)|^2, \quad \Delta_T^2(q) = \frac{2q^3}{\pi^2} |\gamma_q(0)|^2,$$

where  $\gamma_q(0)$  and  $\zeta_q(0)$  are the **constant late-time values** of the cosmological mode functions.

# Non-gaussianity

- Non-Gaussianity is related to **higher-point functions**. In this talk we focus on the three-point function of  $\zeta$ . This is computed using the in-in formalism as

$$\langle \zeta^3(t) \rangle = -i \int_{t_0}^t dt' \langle [\zeta^3(t), H_{int}(t')] \rangle$$

where  $H_{int}$  is obtained by expanding the action to cubic order.

- This leads to

$$\langle \zeta_{q_1} \zeta_{q_2} \zeta_{q_3} \rangle = (2\pi)^3 \delta(q_1 + q_2 + q_3) B(q_1, q_2, q_3)$$

Different models are characterized by different  $B(q_1, q_2, q_3)$ .

# Response functions

Let us now reformulate these results in terms of **response functions**.

- The response functions,  $\Omega_2, \Omega_3, E_2, \dots$ , are defined by

$$\Pi(\vec{x}_1) = \int d^3x_2 \Omega_2(\vec{x}_1 - \vec{x}_2) \zeta(\vec{x}_2) + \int d^3x_2 d^3x_3 \Omega_3(\vec{x}_2 - \vec{x}_1, \vec{x}_3 - \vec{x}_1) \zeta(\vec{x}_2) \zeta(\vec{x}_3) + \dots$$

$$\Pi_{ij}^\gamma(\vec{x}_1) = \int d^3x_2 E_2(\vec{x}_1 - \vec{x}_2) \gamma_{ij}(\vec{x}_2) + \dots,$$

where  $\Pi$  and  $\Pi_{ij}^\gamma$  are the **canonical momenta** of  $\zeta$  and  $\gamma_{ij}$  and the dots indicate other terms that are quadratic and higher order in fluctuations.

# Perturbation equations

The field equations can be written in terms of response functions and we present here the ones associated with  $\zeta$ :

$$0 = \dot{\Omega}_2(q) + \frac{1}{2a^3\epsilon}\Omega_2^2(q) - 2a\epsilon q^2,$$

$$0 = \dot{\Omega}_3(q_i) + \frac{1}{2a^3\epsilon}(\Omega_2(q_1) + \Omega_2(q_2) + \Omega_2(q_3))\Omega_3(q_i) + \mathcal{X}(q_i),$$

where  $\mathcal{X}(q_i)$  depends on the interactions,  $\epsilon = 2(H'/H)^2$  and  $H$  is the Hubble function.

- The cubic in fluctuations Hamiltonian is of the form

$$H_{int} = \int (\mathcal{A}\zeta^3 + \mathcal{B}\Pi\zeta^2 + \mathcal{C}\Pi^2\zeta + \mathcal{D}\Pi^3)$$

→ The coefficients  $\mathcal{A}, \mathcal{B}, \mathcal{C}, \mathcal{D}$  depend on the theory under consideration.

- Then

$$\begin{aligned} \mathcal{X}(q_i) = & 3\mathcal{A}_{123} + \mathcal{B}_{123}\Omega_2(q_1) + \mathcal{B}_{213}\Omega_2(q_2) + \mathcal{B}_{312}\Omega_2(q_3) + \mathcal{C}_{123}\Omega_2(q_2)\Omega_2(q_3) \\ & + \mathcal{C}_{213}\Omega_2(q_1)\Omega_2(q_3) + \mathcal{C}_{312}\Omega_2(q_1)\Omega_2(q_2) + 3\mathcal{D}_{123}\Omega_2(q_1)\Omega_2(q_2)\Omega_2(q_3) \end{aligned}$$

where  $\mathcal{C}_{213} = \mathcal{C}(q_2, q_1, q_3)$ , *etc.*

# Solution

The equations for the response functions can be solved:

- $\Omega_2(q) = 2a^3 \epsilon \dot{\zeta}_q / \zeta_q$
- $\Omega_3(z, q_i) = - \left( \prod_i 1 / \zeta_{q_i}(z) \right) \int_{z_0}^z dz' \mathcal{X}(z', q_i) \prod_i \zeta_{q_i}(z')$ ,

where  $\zeta_q$  is a solution of the *linearised* equation of motion

$$0 = \ddot{\zeta}_q + (3H + \dot{\epsilon}/\epsilon) \dot{\zeta}_q - a^{-2} q^2 \zeta_q,$$

# Response functions and 2- and 3-point functions

- One can show that

$$|\zeta_q|^{-2} = -2\text{Im}[\Omega_2(q)], \quad |\gamma_q|^{-2} = -4\text{Im}[E_2(q)].$$

so the power spectra can be expressed in terms of the **late time behavior of the response functions**.

- One can also show that

$$B(q_1, q_2, q_3) \sim \frac{\text{Im}[\Omega_3(q_1, q_2, q_3)]}{\prod_{i=1}^3 \text{Im}[\Omega_2(q_i)]}$$

evaluated at late times.

We will next show that  $\Omega_2(q)$ ,  $E_2(q)$  and  $\Omega_3(q_1, q_2, q_3)$  are related to **two-** and **three-point** functions of a **strongly coupled 3d QFT**.

# Domain-wall/cosmology correspondence

The springboard for our discussion is a correspondence between cosmologies and domain-wall spacetimes.

- Domain-wall spacetime:

$$\begin{aligned} ds^2 &= dr^2 + e^{2A(r)} dx^i dx^i \\ \Phi &= \Phi(r) \end{aligned}$$

- This solves the field equations that follow from

$$S_{DW} = \frac{1}{2\bar{\kappa}^2} \int d^4x \sqrt{g} [-R + (\partial\Phi)^2 + 2\bar{\kappa}^2 \bar{V}(\Phi)],$$

# Domain-wall/cosmology correspondence

- One can prove the following:

## Domain-wall/Cosmology correspondence

For **every domain-wall** solution of a model with **potential  $\bar{V}$**  there is a **FRW solution** for a model with **potential  $(V = -\bar{V})$** . [Cvetic, Soleng (1994)], [KS, Townsend (2006)]

- The correspondence can be understood as **analytic continuation**. The flip in the sign of  $V$  guarantees that the metric remains real.
- An equivalent way to state the correspondence is

$$\bar{\kappa}^2 = -\kappa^2$$

# Domain-walls and holography

Domain-wall spacetimes enter prominently in holography. They describe **holographic RG flows**.

- The  $AdS_{d+1}$  metric is the unique metric whose **isometry group** is the same as the **conformal group in  $d$  dimensions**. This is the main reason why the bulk dual of a **CFT** is  $AdS$ .
- The **domain-wall** spacetimes are the most general solutions whose **isometry group** is the **Poincaré group in  $d$  dimensions**. Thus, if a **QFT** has a holographic dual the bulk solution must be of **the domain-wall type**.

# Holographic RG flows

There are two different types of domain-wall spacetimes whose holographic interpretation is fully understood.

- 1 The domain-wall is **asymptotically**  $AdS_{d+1}$ ,

$$A(r) \rightarrow r, \quad \Phi(r) \rightarrow 0, \quad \text{as } r \rightarrow \infty$$

This corresponds to a QFT that in the UV approaches a **fixed point**. The fixed point is the **CFT** which is dual to the  $AdS$  spacetime approached as  $r \rightarrow \infty$ .

# Holographic RG flows

## 2 The domain-wall has the following asymptotics

$$A(r) \rightarrow n \log r, \quad \Phi(r) \rightarrow \sqrt{2n} \log r, \quad \text{as } r \rightarrow \infty$$

This case has only been understood recently [Kanitscheider, KS, Taylor (2008)] [Kanitscheider, KS (2009)].

- Specific cases of such spacetimes are ones obtained by taking the **near-horizon limit** of the **non-conformal branes** (D0, D1, F1, D2, D4).
- These solutions describe QFTs with a **"generalized conformal structure"**: all terms in the action **have the same scaling** and there is a **dimensionful** coupling constant.

# Domain-wall/cosmology correspondence

Let us see how the correspondence acts on the domain-walls describing **holographic RG flows**.

- 1 Asymptotically AdS domain-walls are mapped to **inflationary cosmologies** that approach **de Sitter spacetime** at late times,

$$ds^2 \rightarrow ds^2 = -dt^2 + e^{2t} dx^i dx^i, \quad \text{as } t \rightarrow \infty$$

- 2 The second type of domain-walls is mapped to solutions that approach **power-law scaling solutions** at late times,

$$ds^2 \rightarrow ds^2 = -dt^2 + t^{2n} dx^i dx^i, \quad \text{as } t \rightarrow \infty$$

# Outline

## 1 Introduction

## 2 Part I: Holographic dictionary

- Cosmological Perturbations
- The domain-wall/cosmology correspondence
- **Holography: a primer**
- Correlators for holographic RG flows
- Holography for cosmology

## 3 Part II: New holographic models

## 4 Conclusions

# Holography: a primer

The holographic dictionary for cosmology will be based on the standard holographic dictionary, so we now briefly review standard holography:

- 1 There is 1-1 correspondence between **local gauge invariant operators**  $\mathcal{O}$  of the boundary QFT and **bulk supergravity modes**  $\Phi$ .
  - The **bulk metric** corresponds to the **energy momentum tensor** of the boundary theory.
- 2 **Correlation functions** of gauge invariant operators can be extracted from the **asymptotics** of bulk solutions.

# Asymptotic solutions

- The standard gauge/gravity duality is based on spacetimes that are **asymptotically locally Anti-de Sitter**.
- These spacetimes have a **conformal boundary** and **near the conformal boundary** Einstein equations (with negative cosmological constant) hold.
- This implies that the metric has the following asymptotic form (in 4 bulk dimensions) [**Fefferman, Graham (1985)**]

$$ds^2 = dr^2 + e^{2r} g_{ij}(x, r) dx^i dx^j$$

$$g_{ij}(x, r) = \mathbf{g}_{(0)ij}(\mathbf{x}) + e^{-2r} g_{(2)ij}(x) + e^{-3r} g_{(3)ij}(x) + \dots$$

- $\mathbf{g}_{(0)}(\mathbf{x})$  is the **metric of the spacetime where the boundary theory lives** and (as such) it is also the **source of the boundary energy momentum tensor**.

# Correlation functions

- Using the formalism of **holographic renormalization**, we then find a precise relation between correlation functions and asymptotics [de Haro, Solodukhin, KS (2000)]

$$\langle T_{ij} \rangle = \frac{3}{2\kappa^2} g^{(3)ij}.$$

- This formula only requires that Einstein equations hold **near the conformal boundary**. *In particular, it is also valid when curvatures are large in the interior.*
- Higher-point functions** are obtained by differentiating the 1-point functions w.r.t. sources and then setting the sources to their background value

$$\langle T_{i_1 j_1}(x_1) T_{i_2 j_2}(x_2) \cdots T_{i_n j_n}(x_n) \rangle \sim \frac{\delta^{(n-1)} g^{(3) i_1 j_1}(x_1)}{\delta g_{(0) i_2 j_2}(x_2) \cdots \delta g_{(0) i_n j_n}(x_n)} \Big|_{g_{(0)} = \eta}$$

# Correlation functions

Thus to **solve the theory** we need to know  $g_{(3)}$  as a function of  $g_{(0)}$ . This can be obtained perturbatively.

→ From gravity to QFT

**2-point functions** are obtained by solving **linearized fluctuations**, **3-point functions** by solving **quadratic fluctuations** etc. Here it is crucial that the gravitational approximation is valid and this results in correlators of **strongly coupled QFT**.

→ From QFT to gravity

Given QFT correlators one obtains an **asymptotic solution**. If the QFT correlators are that of **weakly coupled QFT** then the bulk description has **the prescribed asymptotic behavior** and is **strongly coupled in the interior**.

# Outline

## 1 Introduction

## 2 Part I: Holographic dictionary

- Cosmological Perturbations
- The domain-wall/cosmology correspondence
- Holography: a primer
- **Correlators for holographic RG flows**
- Holography for cosmology

## 3 Part II: New holographic models

## 4 Conclusions

# Correlation functions for holographic RG flows

- To compute correlation functions we perturb around the domain-wall. The linearized equations are given by [Bianchi, Freedman, KS (2001)], [Papadimitriou, KS (2004)],

$$\begin{aligned}0 &= \ddot{\zeta} + (3H + \dot{\epsilon}/\epsilon)\dot{\zeta} - \bar{q}^2 e^{-2A}\zeta \\0 &= \ddot{\gamma}_{ij} + 3H\dot{\gamma}_{ij} - \bar{q}^2 e^{-2A}\gamma_{ij},\end{aligned}$$

- Comparing with the cosmological perturbations, we find that the equations are mapped to each other provided

$$\bar{q} = -iq$$

- The same holds to all order: the fluctuation equations are mapped to each other provided the momenta are continued as above.

# Correlation functions for holographic RG flows

We now want to extract 2- and 3-point functions.

- Schematically, we must expand the perturbed solution near  $r \rightarrow \infty$  and extract the piece that scales like  $e^{-3r}$ .
  - The part **linear in fluctuation** gives the 2-point function.
  - The part **quadratic in fluctuation** gives the 3-point function.
- It is convenient to work in terms of **response functions** [Papadimitriou, KS (2004)]

$$\bar{\Pi} = -\bar{\Omega}_2 \zeta - \bar{\Omega}_3 \zeta^2 + \dots, \quad \bar{\Pi}_{ij}^\gamma = -\bar{E}_2 \gamma_{ij} + \dots,$$

where  $\bar{\Pi}, \bar{\Pi}_{ij}^\gamma$  are **radial canonical momenta**.

## 2-point functions for holographic RG flows

The 2-point function of the energy momentum tensor is then given by

$$\langle T_{ij}(\bar{q}) T_{kl}(-\bar{q}) \rangle = A(\bar{q}) \Pi_{ijkl} + B(\bar{q}) \pi_{ij} \pi_{kl},$$

where  $\Pi_{ijkl} = \frac{1}{2}(\pi_{ik}\pi_{lj} + \pi_{il}\pi_{kj} - \pi_{ij}\pi_{kl})$ ,  $\pi_{ij} = \delta_{ij} - \bar{q}_i \bar{q}_j / \bar{q}^2$ .

$$A(\bar{q}) = 4 [\bar{E}_2(\bar{q})]_{(0)}, \quad B(\bar{q}) = \frac{1}{4} [\bar{\Omega}_2(\bar{q})]_{(0)}.$$

The subscript indicates that one should pick the term with **appropriate scaling** in the asymptotic expansion.

## 3-point functions for holographic RG flows

- Similarly, one can derive a holographic formula for the 3-point function

$$\langle T_{i_1 j_1}(\bar{q}_1) T_{i_2 j_2}(\bar{q}_2) T_{i_3 j_3}(\bar{q}_3) \rangle = \dots$$

in terms of response functions.

- The 3-point function for the **trace of stress energy tensor**,  $T = T_i^i$ , is related to the response function  $\Omega_3$  by

$$[\Omega_3(\bar{q}_1, \bar{q}_2, \bar{q}_3)]_{(0)} \sim \langle T(\bar{q}_1) T(\bar{q}_2) T(\bar{q}_3) \rangle + \sum_i \langle T(\bar{q}_i) T(-\bar{q}_i) \rangle - 2[\langle T(\bar{q}_1) \Upsilon(\bar{q}_2, \bar{q}_3) \rangle + \langle T(\bar{q}_2) \Upsilon(\bar{q}_1, \bar{q}_3) \rangle + \langle T(\bar{q}_3) \Upsilon(\bar{q}_1, \bar{q}_2) \rangle].$$

where

$$\Upsilon(\vec{x}_1, \vec{x}_2) = \left. \frac{\delta T_{ij}(\vec{x}_1)}{\delta g^{kl}(\vec{x}_2)} \right|_0 \delta^{ij} \delta^{kl}.$$

# Outline

- 1 Introduction
- 2 Part I: Holographic dictionary
  - Cosmological Perturbations
  - The domain-wall/cosmology correspondence
  - Holography: a primer
  - Correlators for holographic RG flows
  - Holography for cosmology
- 3 Part II: New holographic models
- 4 Conclusions

# Holography for cosmology

We are now ready to present the holographic dictionary for cosmology.

- The DW/cosmology correspondence maps the **near boundary region** to the **late time region**.
- Under the analytic continuation

$$\bar{\kappa}^2 = -\kappa^2, \quad \bar{q} = -iq$$

the response functions continue as follows

$$\begin{aligned}\bar{\Omega}_2(\bar{q}) &= \Omega_2(-iq), & \bar{E}_2(\bar{q}) &= E_2(-iq), \\ \bar{\Omega}_3(\bar{q}_1, \bar{q}_2, \bar{q}_3) &= \Omega_3(-iq_1, -iq_2, -iq_3).\end{aligned}$$

- The analytic continuations translate in QFT language to

$$\bar{N} \rightarrow -iN, \quad \bar{q} \rightarrow -iq$$

# Holographic dictionary: Power spectrum

- We have shown earlier that

$$\Delta_S^2(q) = \frac{-q^3}{4\pi^2 \text{Im}\Omega_{(0)}(q)}, \quad \Delta_T^2(q) = \frac{-q^3}{2\pi^2 \text{Im}E_{(0)}(q)},$$

It follows

$$\Delta_S^2(q) = \frac{q^3}{2\pi^2} \left( \frac{-1}{8\text{Im}B(-iq)} \right), \quad \Delta_T^2(q) = \frac{2q^3}{\pi^2} \left( \frac{-1}{\text{Im}A(-iq)} \right),$$

where the holographic 2-point function is

$$\langle T_{ij}(\bar{q}) T_{kl}(-\bar{q}) \rangle = A(\bar{q}) \Pi_{ijkl} + B(\bar{q}) \pi_{ij} \pi_{kl},$$

# Holographic dictionary: Non-Gaussianity

- We have seen earlier that

$$\langle \zeta_{q_1} \zeta_{q_2} \zeta_{q_3} \rangle = (2\pi)^3 \delta(q_1 + q_2 + q_3) B(q_1, q_2, q_3)$$

and  $B(q_1, q_2, q_3) \sim \text{Im}[\Omega_3(q_1, q_2, q_3)] / \prod_{i=1}^3 \text{Im}[\Omega_2(q_i)]$ .

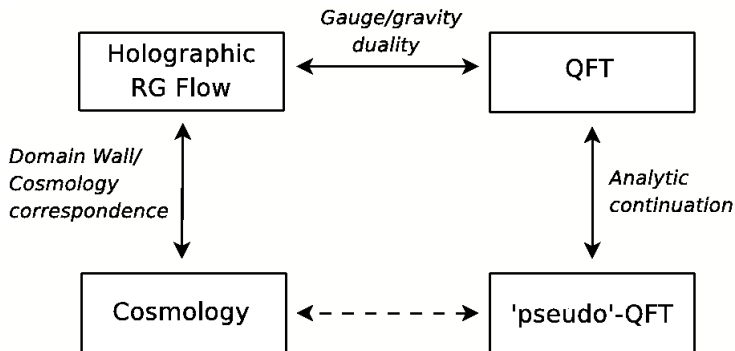

- It follows

$$B(q_1, q_2, q_3) = -\frac{1}{4} \frac{1}{\prod_i \text{Im}\langle T(\bar{q}_i) T(-\bar{q}_i) \rangle} \cdot \text{Im} \left[ \langle T(\bar{q}_1) T(\bar{q}_2) T(\bar{q}_3) \rangle + \sum_i \langle T(\bar{q}_i) T(-\bar{q}_i) \rangle - 2(\langle T(\bar{q}_1) \Upsilon(\bar{q}_2, \bar{q}_3) \rangle + \text{cyclic perms}) \right],$$

where the imaginary part is taken after the analytic continuation.

# Summary

# Outline

- 1 Introduction
- 2 Part I: Holographic dictionary
  - Cosmological Perturbations
  - The domain-wall/cosmology correspondence
  - Holography: a primer
  - Correlators for holographic RG flows
  - Holography for cosmology
- 3 Part II: New holographic models
- 4 Conclusions

# New holographic models

- We are now going to obtain new models by using **weakly coupled QFT**. This correspond to the gravitational theory being **strongly coupled at early times**.
- The boundary theory will be a combination of **gauge fields, fermions and scalars** and it should admit a **large  $N$  expansion**.
- To extract predictions we need to compute  $n$ -point functions of the stress energy tensor **analytically continue the result** and **insert them in the holographic formulae**.

# The holographic model

- As a model one can consider the strong coupling version of **asymptotically dS cosmologies** and **power-law cosmology**.
- In this work we focus on QFTs dual to the latter. These are **super-renormalizable** QFTs that depend on a single **dimensionful coupling**:

$$S = \frac{1}{g_{\text{YM}}^2} \int d^3x \text{tr} \left[ \frac{1}{2} F_{ij}^I F^{Iij} + \frac{1}{2} (D\phi^J)^2 + \frac{1}{2} (D\chi^K)^2 + \bar{\psi}^L \not{D} \psi^L \right. \\ \left. + \lambda_{M_1 M_2 M_3 M_4} \Phi^{M_1} \Phi^{M_2} \Phi^{M_3} \Phi^{M_4} + \mu_{ML_1 L_2}^{\alpha\beta} \Phi^M \psi_\alpha^{L_1} \psi_\beta^{L_2} \right].$$

- All terms in this Lagrangian have **dimension 4**.

# A new mechanism for scale invariant spectrum

We need to compute the 2-point function of  $T_{ij}$ . The leading order computation is at 1-loop:

The answer follows from general considerations:

- The stress energy tensor has **dimension 3** in **three dimensions**.
- 1-loop amplitudes are independent of  $g_{YM}^2$
- There is a factor of  $\bar{N}^2$  because of the trace over the gauge indices.

$$\langle T_{ij} T_{kl} \rangle \sim \bar{N}^2 \bar{q}^3$$

# A new mechanism for scale invariant spectrum

Recalling the holographic map:

$$\Delta_S^2 \sim \frac{\bar{q}^3}{\langle TT \rangle} \sim \frac{1}{N^2}$$

- Spectrum is scale invariant to leading order, independent of the details of the holographic theory.

Furthermore,

- Amplitude of power spectrum  $\mathcal{A} \sim 1/N^2$ .
- Small  $\mathcal{A} \sim 10^{-9} \Rightarrow$  large  $N \sim 10^4$ , justifying the large  $N$  limit.

# Power spectra

The complete answer is

$$A(\bar{q}) = C_A \bar{N}^2 \bar{q}^3 + O(g_{\text{YM}}^2), \quad B(\bar{q}) = C_B \bar{N}^2 \bar{q}^3 + O(g_{\text{YM}}^2),$$

where

$$C_A = (\mathcal{N}_A + \mathcal{N}_\phi + \mathcal{N}_\chi + 2\mathcal{N}_\psi)/256, \quad C_B = (\mathcal{N}_A + \mathcal{N}_\phi)/256.$$

It follows

$$\Delta_S^2(q) = \frac{1}{16\pi^2 N^2 C_B} + O(g_{\text{YM}}^2), \quad \Delta_T^2(q) = \frac{2}{\pi^2 N^2 C_A} + O(g_{\text{YM}}^2).$$

$\mathcal{N}_A$  : # of gauge fields,  $\mathcal{N}_\phi$  : # of minimally coupled scalars,  
 $\mathcal{N}_\chi$  : # of conformally coupled scalars,  $\mathcal{N}_\psi$  : # of fermions.

# Tensors-to-scalar ratio

- It follows that

$$r = \Delta_T^2 / \Delta_S^2 = 32C_B / C_A,$$

- This is not parametrically suppressed as in slow-roll inflation, nor does it satisfy the conventional slow-roll consistency condition  $r = -8n_T$ .
- An upper bound on  $r$  translates into a **constraint on the field content of the dual QFT**.
- A smaller upper bound on  $r$  requires increasing the number of conformal scalars and massless fermions and/or decreasing the number of gauge fields and minimal scalars.

# Subleading corrections

Subleading corrections give small deviations from scale invariance:

$$n_s - 1 \sim g_{\text{eff}}^2 = g_{\text{YM}}^2 N/q.$$

The observational value  $(n_s - 1) \sim 10^{-2}$  is then consistent with the QFT being weakly interacting.

- To determine the **sign of  $(n_s - 1)$**  (positive: red-tilted spectrum, negative: blue-tilted spectrum) requires summing all 2-loop graphs, and will in general depend on the field content of the dual QFT.

*[Work in progress]*

## 2-loop details

Super-renormalizable theories often have **infrared problems**. The specific type of theories we consider however are well-defined:  $g_{YM}^2$  acts as an infrared cut-off. [Jackiw, Templeton (1981)] [Appelquist, Pisarski (1981)].

The 2-loop integrals are indeed **finite** and one obtains:

$$A(\bar{q}) = C_A \bar{N}^2 \bar{q}^3 [1 + D_A g_{\text{eff}}^2 \ln \bar{q}/\bar{q}_0 + O(g_{\text{eff}}^4)],$$

$$B(\bar{q}) = C_B \bar{N}^2 \bar{q}^3 [1 + D_B g_{\text{eff}}^2 \ln \bar{q}/\bar{q}_0 + O(g_{\text{eff}}^4)],$$

where  $g_{\text{eff}}^2 = g_{YM}^2 \bar{N}/\bar{q}$  and  $D_A$  and  $D_B$  are numerical constants. This leads to

$$n_S(q) - 1 = -D_B g_{\text{eff}}^2 + O(g_{\text{eff}}^4), \quad n_T(q) = -D_A g_{\text{eff}}^2 + O(g_{\text{eff}}^4).$$

# Running

- Independent of the details of the theory, the scalar spectral index runs as

$$\alpha_s = \frac{dn_s}{d \ln q} = -(n_s - 1) + O(g_{\text{eff}}^4).$$

- This prediction is qualitatively different from slow-roll inflation, for which  $\alpha_s/(n_s - 1)$  is of first-order in slow-roll.
- This prediction is consistent with current data and Planck should be able to either exclude or confirm this running.

# WMAP data

## WMAP Cosmological Parameter Plotter

Solid line:

$$\alpha = -(n_s - 1)$$

# Non-Gaussianity

Direct computation gives

$$\begin{aligned} \langle T(\bar{q}_1)T(\bar{q}_2)T(\bar{q}_3) \rangle &+ \sum_i \langle T(\bar{q}_i)T(-\bar{q}_i) \rangle \\ &- 2(\langle T(\bar{q}_1)\Upsilon(\bar{q}_2, \bar{q}_3) \rangle + \text{cyclic perms}) \\ &= 2C_B \bar{N}^2 (2\bar{q}_1\bar{q}_2\bar{q}_3 + \sum_i \bar{q}_i^3 - (\bar{q}_1\bar{q}_2^2 + 5 \text{ perms})) \end{aligned}$$

- Using the holographic formula one finds

$$B(q_1, q_2, q_3) = B_{NL}^{\text{equil}}(q_1, q_2, q_3)$$

with

$$f_{NL}^{\text{equil}} = 5/36$$

- This is **independent of all details of theory**.
- This value is larger than the  $f_{NL}$  for slow-roll inflation, but probably still too small to be detected by Planck.

# Outline

- 1 Introduction
- 2 Part I: Holographic dictionary
  - Cosmological Perturbations
  - The domain-wall/cosmology correspondence
  - Holography: a primer
  - Correlators for holographic RG flows
  - Holography for cosmology
- 3 Part II: New holographic models
- 4 Conclusions

# Conclusions

- I have presented a holographic description of inflationary cosmology in terms of a **3-dimensional QFT (without gravity!)**
- When gravity is **weakly coupled**, holography correctly reproduces **standard inflationary predictions** for cosmological observables.
- When gravity is **strongly coupled**, one finds **new models** that have a QFT description.

# Observational signatures

I presented models with the following universal features:

1. they have a **nearly scale invariant spectrum** of **small amplitude** primordial fluctuations.
2. the scalar spectral index runs as  $\alpha_s = -(n_s - 1)$ .
3. the three point function of curvature perturbations is exactly equal to the equilateral form with  $f_{NL}^{\text{equil}} = 5/36$ .

Both predictions 2 and 3 could easily be ruled out by the Planck data next year.

# Outlook

“If we pull this off, we’ll eat like kings.”

## DW/cosmology correspondence [KS, Townsend (2006)]

- FRW spacetime ( $k = 0, -1, +1$ )

$$ds^2 = -dt^2 + a(t)^2 \left( \frac{dr^2}{1 - kr^2} + r^2(d\theta^2 + \sin^2\theta d\Omega_{d-2}^2) \right)$$

- Curved domain-wall ( $\kappa = 0, -1, +1$ )

$$ds^2 = dz^2 + e^{2A(z)} \left( -\frac{d\tau^2}{1 + \kappa\tau^2} + \tau^2(d\psi^2 + \sinh^2\psi d\Omega_{d-2}^2) \right)$$

- The analytic continuation

$$(t, r, \theta) = -i(z, \tau, \psi)$$

maps the one solution to the other with

$$a(t) \leftrightarrow e^{A(z)}, \quad k \leftrightarrow -\kappa$$
